

UNEXMIN DELIVERABLE D5.2

UX1 STAKEHOLDER REQUIREMENT SPECIFICATION

Summary

Constraints and requirements for UX1 design are set by needs of two stakeholder groups: Internal stakeholders and external stakeholders. This requirement specification document is based on requirements and constraints derived from needs of these two stakeholder groups. Specification identifies and states key requirements set by needs of potential stakeholders and operation environments and mission types in their interest. This report does not aim to providing design specifications or exact technical requirements, but a basis for generating them.

1 Introduction

Constraints and requirements for UX1 design are set by needs of two stakeholder groups: Internal stakeholders, i.e. UNEXMIN project partners providing a test site, and external stakeholders, i.e. potential end-users, operators and their potential clientele. The first group has provided their insight in preliminary specifications presented in research plan and meeds of the latter group has been studied by questionnaire distributed among potential external stakeholders. This requirement specification document is based on requirements and constraints derived from needs of these two stakeholder groups.

1.1 Description of UX1 and its mission

There are number of abandoned old flooded mines in Europe, with inadequate information of their current status. Exploring and surveying such mines is both infeasible and hazardous for humans. UX1 is an autonomous robotic platform for survey and exploration of such mines. UX1 is to autonomously explore and survey such mines in order to provide high resolution data and information from these inaccessible environments. This data should provide mapping and morphological information of the mine along with geological information as required by the end users.

1.2 Scope of this report

This report identifies and states key requirements set by needs of potential stakeholders and operation environments and mission types in their interest. This report does not aim to providing design specifications or exact technical requirements, but a basis for generating them.

2 Environmental constraints and considerations

- **1.**Mine tunnels and other openings are narrow which must be considered both in designing manoeuvrability of the robot but also in hauling robot itself and support equipment inside the mine.
- **2.**Water inside the mine is not always transparent and any contact with the underwater walls result in increased turbidity of water due to silt.
- **3.**The water quality variations are high. Water might also be acidic; hence the external equipment of the robot must be made of acid resistant materials.
- **4.**Water temperature variation: +4... 40°C.
- **5.**Local water flow velocity can be high.
- 6.Maximum depth: 500 m.
- **7.**The walls and cavities of mines can be unstable; therefore the robot operation must be contactless and be able to reverse out of dead ends channels.
- **8.**Mine tunnels are predominantly vertical shafts or mainly horizontal galleries (although with the possibility of having slight inclination in some places).
- **9.**Horizontal galleries can vary in dimensions. For smaller galleries (older mines) the height is usually larger than the width. Tunnels in general have height and width not bigger than 5m.
- **10.**There is also a possibility of having at some locations wider underground spaces (either in galleries or at junctions). In these locations the width can exceed over 10m.
- **11.**Maximum Manhattan distance from any point of the mine to entrance at water surface is under 2.5 km.

Chapter 4 gives detailed information on last three test sites of UNEXMIN-project. These sites have in large extent defined preliminary requirements.

3 Requirements for robot characteristics

- **1.**Revolution shape if possible without external protuberances (such as spherical or cylindrical shape) allowing manoeuvrability in tight spaces.
- **2.**The robot body should be streamlined to reduce drag and reduce probability of getting stuck.
- 3. Maximum diameter 600 mm to be able to navigate through narrow channels.
- 4. Modular design (can be adapted to different missions or scenarios).
- 5. Easy transportation, hauling and deployment
- **6.**The robot must possess high manoeuvrability while driving through constrained spots.
- **7.**The power unit should be capable of supporting the robot for 5 hours of driving autonomously.
- **8.** Distance covered with single charge 1 5 km.
- **9.**The propulsion unit must provide enough thrust in order to drive the robot with 0.5 m/s velocity under 50 bar pressure.
- **10.**The vision system should be able to map the wall surfaces 360 degrees perpendicular to the motion direction and be capable of navigating in turbid water (have complementary sensors for range information).
- **11.**The vision system should be able to map the wall surfaces 360 degree and take images also in turbid water.
- **12.**Due to the lack of absolute positioning systems, robot navigation must be environment based (based on perception). Varying water turbidity and extreme environment conditions require multiple navigation sensor systems providing information to be fused. These can include, multibeam sonar, sector scan sonar, vision based systems with structured light and INS coupled with DVL with fluid current measurement capability.
- **13.**The robot must be capable of constant communication with a base station during the mission while the robot is up to 500 meters underwater.
- **14.**The robot controller unit must provide autonomous operation, power monitoring, and fault detection for safety purposes.
- **15.**The robot should be equipped with certain sensors in order to analyse walls and water. These sensors can include for example:
 - •Hyperspectral / LIBS for mineral and geochemistry mapping.
 - •Gamma ray for lithology mapping
 - •Video and Camera (stereo).
 - •Thermal sensor
 - •Pressure sensor.
 - •pH and Eh
 - •Fiber optic sensors for water quality
- 16.Robot must have a water sampling system

17. The robot batteries can be loaded or charged while the robot is in water.

- **18.**The robot must have the key functionalities:
 - -Create an online map of the environment for navigation purposes
 - -Record time stamped and synchronous mapping and application sensor data for mission post-processing
 - -Use previous information about the map: both historical information from the mine or from previous surveys, incrementally.

- -The robot's perception system should be able to perceive thin obstacles such as ropes or cables.
- -Be able to move lateral and vertical to avoid obstacles
- -Has specific survey manoeuvres to move close (parallel and at a known distance) of mine walls; to move in tunnels and galleries avoiding obstacles; to do scanning motion to map tunnels and galleries with multibeam; to reverse direction or move back in closed small tunnels.
- **19.**The mission design system should allow the operator to specify the type of mission and the parametrization of the robot exploration methods.
- **20.**The robot system should have a wireless communication for easy setup and parametrization.

Remarks:

TEST SITE CHARACTERIZATION		
Type of mining exploitation: Underground.	Exploited ores: Formerly chalcopyrite (Cu)	
Mineral deposit type: Formerly Cu + some Pb & Zn	Host rocks: Limestone.	
Mining period: 1500 BC – 1880 AD	Current accessibility by: Adit	
General mine description : Access adit (Deep Ecton) is level but wet in places (0.3m deep) to all flooded working for UNEXMIN use and the water level in these is close to floor level. One accessible level above Deep Ecton (Salts Level) access by different surface adit. Ladder link between them (37m) - prohibited.		
What are most important parts of the mine to explore: Three flooded shafts and the worked out mineral		
pipe.		
Maximum depth of the mine: ~380m	Is the mine completely flooded?: No	
Maximum know accessible depth: ~80m (Surface to Water depth below the surface: ~300m		
top of water.)		
Minimum diameter of tunnels: Entry >0.6m	Water quality in the mine: Close to ph7 – clean	

Minimum diameter of tunnels: Entry >0.6m	Water quality in the mine: Close to ph7 – clean.
Maximum original continuous shaft length: ~300m	Known water temperature in the mine: 10°C
Maximum known continuous shaft length accessible	Water temperature range in the mine:
for testing: ~300m	$10^{\circ} \pm 5^{\circ}$ C estimated
Maximum original continuous gallery length:	Maximum known water flow velocity in galleries:
~500m.	Negligible
Maximum known and continuous gallery length	Presence of gases inside non-flooded galleries:
accessible for testing: Unknown.	None – Some prohibited areas O ₂ deficient.
How leveled are the galleries? Uneven floors.	Known living beings growing in the mine: None
Type of obstacles in the galleries and shafts: Uneven	Possibility of soft obstacles in shafts and galleries
floors with some water up to 0.3m deep.	which might not be detected by sensors: Some
	wooden structures & wood/iron ladders
How hard it is to get from surface to water level?	Other remarks: The mine is a listed/protected
Walk of 300m. Entry level is main drainage level and	'Ancient Monument'. All prohibited hazardous
entry with steep 1m slope.	areas marked.
EXISTENT FACILITIES	
Available electricity: Underground electricity to be	Available water: None.
installed 240V, 50Hz 1 phase. Lighting to be installed	
in working areas

TEST SITE CHARACTERIZATION		
Type of mining exploitation: underground	Exploited ores: cinnabar ore, native mercury	
Mineral deposit type: epithermal	Host rocks: different types of sedimentary rocks (sandstones, claystone, carbonates, tuff)	
Mining period: -1490 - 1995	Current accessibility by: Vertical shaft	

General mine description: The Idrija Mercury Mine was one of the largest and oldest mercury mines in the world and is operated since 1490. During its 500-year tradition it was, due to the high price and the strategic importance of mercury, always the leading center of the technological development of mining technology in the world. The Hg mineralization is found in the complex stratigraphic sequence, including claystones, mudstones, sandstones, conglomerates, limestones or similar sedimentary rocks, which are geotechnically not very favorable for mine development. Therefore, narrow passages and a lot of supporting measures are found in this mine. Estimates are that during of mine lifetime it produced 12.7 Mt of cinnabar ore and 145 000 t of Hg, which means that 13% of total historic world Hg production comes from Idrija. The mine reached its depth of 460 m below the surface, and 700 km of tunnels were excavated. The production of mercury stopped in 1995. Today the Idrija heritage of mercury and the Idrija Ore deposit among it is listed on UNESCO World heritage list.

What are most important parts of the mine to explore: shaft and horizontal submerged tunnels

Maximum depth of the mine: cca m 381 m	Is the mine completely flooded?: no, flooded part is level IX and below
Maximum know accessible depth: cca 270 m	Water depth below the surface: 206 m
Minimum diameter of tunnels: cca 2 m, but debris or collapsed rocks can reduce it	Water quality in the mine: Fe (7.2 mg/l), SO4 (4300 mg/l), Hg (90 ng/l)
Maximum original continuous shaft length: 271 m	Known water temperature in the mine: 17 deg. C
Maximum known continuous shaft length accessible	Water temperature range in the mine:
for testing: unknown	no fluctuations
Maximum original continuous gallery length: not relevant for testing (collapsed)	Maximum known water flow velocity in galleries: Unknown (probably negligent).
Maximum known and continuous gallery length accessible for testing: not relevant for testing (collapsed)	Presence of gases inside non-flooded galleries: Radon, CO2, mercury vapors.
How leveled are the galleries? Originally well leveled	Known living beings growing in the mine: None, except bacteria and fungus.
Type of obstacles in the galleries and shafts: Eventual wood and iron structures and mine galleries collapses. Narrow access passage (0.5 m), platforms (steel bars).	Possibility of soft obstacles in shafts and galleries which might not be detected by sensors: Eventual wood residues steel bars (platforms) in the shaft
Can the water level be reached from surface	Other remarks:
without special techniques? No. Elevator will be used to reach level III, after that descent by foot on stairs for the next 85 m.	The testing robot will be transported separately with special winch, and finally assembled in the shaft.
EXISTENT FACILITIES	
Available electricity: 1-phase 220V electricity access is on the III. level; 3- phase 380 V electricity access is on the surface	Available water: Drinking water available, wardrobes, offices, mining rescue service, showers and warm water

What are most important parts of the mine to explore: G Maximum depth of the mine:580 m Maximum know accessible depth: unknown Minimum diameter of tunnels:? Maximum original continuous shaft length: 400 m Maximum known continuous shaft length accessible for testing: unknown Maximum original continuous gallery length: 1600 m Maximum known and continuous gallery length accessible for testing: unknown Maximum known and continuous gallery length accessible for testing: unknown How leveled are the galleries? Originally well leveled Type of obstacles in the galleries and shafts: Eventual wood structures and mine galleries collapses	 Is the mine completely flooded?: yes Water depth below the surface: 10 m Water quality in the mine: Average of last 3 years: pH 6,43; conductivity 705 µs/cm; 37 mg/l SO₄; 1,6 mg/l Fe; 4,0 mg/l Mn; 16 mg/l Tss; 0,046 bq/l Ra226; 15,77 ppb U; Known water temperature in the mine: Water temperature range in the mine: Not measured. Dependent on thermal gradient. Maximum known water flow velocity in galleries: Unknown (probably negligent). Presence of gases inside non-flooded galleries: Radon and eventually sulfidic. Known living beings growing in the mine: Unknown. Possibility of soft obstacles in shafts and galleries which might not be detected by sensors: Eventual wood residues.
What are most important parts of the mine to explore: G Maximum depth of the mine:580 m Maximum know accessible depth: unknown Minimum diameter of tunnels:?
